Conclusions

- Tokamak with cylindrical symmetry
- Magnetic field following the geometry
- Anisotropic diffusion depends on the magnetic field and so on the geometry

Aim of this work :

- How develop a Finite Volume method on a variable system coordinates ?
- Advantages and drawbacks compared with cartesian formulation

# Introduction to curvilinear coordinates

3D-PRISM  
project

Physic space :  $\Omega(\vec{x})$     Computational space :  $\Omega(\vec{\xi})$

## Covariant basis

$$\forall i = 1, \dots, n, \quad \underline{e}_{\xi^i} = \frac{\partial x_k}{\partial \xi^i} \underline{e}_{x_k}$$

For example in polar coordinates :

- covariant basis :

$$\underline{e}_r = \begin{pmatrix} \cos \theta \\ \sin \theta \end{pmatrix}, \quad \underline{e}_\theta = \begin{pmatrix} -\sin \theta \\ \cos \theta \end{pmatrix}.$$

- contravariant basis :  $\underline{e}^{\xi^i} \cdot \underline{e}_{\xi^j} = \delta_{i,j}$

Conclusions

Gradient :

$$\frac{\partial \underline{e}^{\xi_i}}{\partial \xi^j} = \Gamma_{i,j}^k \underline{e}_{\xi^k}$$

Divergence operator :

$$\nabla_{\underline{x}} \cdot \underline{f} = \frac{1}{J} \frac{\partial}{\partial \xi^i} (J f^{\xi^i}),$$

Divergence of a tensor field :

$$\nabla_{\underline{x}} \cdot \underline{\underline{T}} = \frac{1}{J} \frac{\partial}{\partial \xi^i} (J \underline{\underline{T}} \cdot \underline{e}^{\xi^i}).$$

## Vectorial equation in polar coordinates

$$\partial_t(r \underline{S}) + \partial_r(r T^{r,r} \underline{e}_r + r T^{r,\theta} \underline{e}_\theta) + \partial_\theta(r T^{\theta,r} \underline{e}_r + r T^{\theta,\theta} \underline{e}_\theta) = 0.$$

How approach this equation ?

- Classical method : Projection before numerical integration  
⇒ Drawback : Source terms appear from hyperbolic term
- Other method : Numerical integration before projection  
⇒ Drawback : Projection choice needed

# Source terms

3D-PRISM  
project

Introduction  
Introduction  
Curvilinear  
coordinates

Numeric  
**Usually**

Simulations  
Scalar  
Vectorial  
Gresho

Conclusions

Vectorial equation in polar coordinates :

$$\partial_t(r \underline{S}) + \partial_r(r T^{r,r} \underline{e}_r + r T^{r,\theta} \underline{e}_\theta) + \partial_\theta(r T^{\theta,r} \underline{e}_r + r T^{\theta,\theta} \underline{e}_\theta) = 0.$$

## Projection

$$\begin{cases} \partial_t(r S_r) + \partial_r(r T^{r,r}) + \partial_\theta T^{r,\theta} = T^{\theta,\theta} \\ \partial_t(r S_\theta) + \partial_r(r T^{r,\theta}) + \partial_\theta T^{\theta,\theta} = -T^{r,\theta} \end{cases}$$

Source terms  $T^{\theta,\theta}$  and  $-T^{r,\theta}$  appear.

⇒ How discretize source terms to have equivalent methods?

Scalar  
Vectorial  
Gresho

Conclusions

## Comparison between the two methods

Equivalent methods if :

$$\int_{\Omega_i} T^{\theta,\theta}(r, \theta) dr d\theta$$
$$= \Delta\theta \Delta r \frac{\hat{T}_{|\theta_B}^{\theta,\theta} + \hat{T}_{|\theta_A}^{\theta,\theta}}{2} + \left(1 - \frac{\Delta\theta}{2} \frac{\sin \Delta\theta}{1 - \cos \Delta\theta}\right) \Delta r (\hat{T}_{|\theta_B}^{\theta,\theta} - \hat{T}_{|\theta_A}^{\theta,\theta})$$

- Usual center term
- Viscosity term

**Differences**

Simulations  
Scalar  
Vectorial  
Gresho

Conclusions

- Meshes
- Geometrical parameters : cell areas, normals
- Fluxes computing : Constants in cell, post-processing

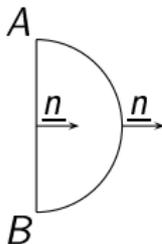

Polar and Cartesian meshes

## Normals in curvilinear coordinates

$$\int_{\partial\Omega_{i,j}(\underline{x})} \underline{n}(\underline{x}) dl(\underline{x}) = \int_{\partial\Omega_{i,j}(\underline{\xi})} J \underline{n}_k(\underline{\xi}) \underline{e}^k dl(\underline{\xi})$$

Divergence theorem on a closed outline :

$$\oint \underline{n} dl = 0 \text{ i.e. } \int_{\widehat{AB}} \underline{n} dl = \int_{\overline{AB}} \underline{n} dl.$$

- Same normal in polar and cartesian coordinates
- The normal depends only on A and B

- Cartesian Coordinates :

$$|\Omega_i|_{x,y} = \left(r + \frac{\Delta r}{2}\right) \Delta r \sin \Delta \theta$$

- Polar coordinates :

$$|\Omega_i|_{r,\theta} = \int_{\Omega_i} r dr d\theta = \left(r + \frac{\Delta r}{2}\right) \Delta r \Delta \theta$$

## Equivalence between polar and cartesian

When  $\Delta \theta$  is small,  $\sin \Delta \theta \approx \Delta \theta$ , so  $|\Omega_i|_{x,y} \approx |\Omega_i|_{r,\theta}$ .

# Constants on a cell

project

Introduction  
Introduction  
Curvilinear  
coordinates

Numeric  
Usually  
Differences

Simulations

Scalar  
Vectorial  
Gresho

Conclusions

- Cartesian coordinates :  
Same flux given to two neighbour points  $i$  and  $j$

$$\underline{\Phi}_i = \Phi^x \underline{e}_x + \Phi^y \underline{e}_y \quad \text{and} \quad \underline{\Phi}_j = \Phi^x \underline{e}_x + \Phi^y \underline{e}_y$$

- Polar coordinates :  
Fluxes depend on the local basis  $(\underline{e}_r, \underline{e}_\theta)$  so different fluxes given to two neighbour points  $i$  and  $j$

$$\underline{\Phi}_i = \Phi^r \underline{e}_{r_i} + \Phi^\theta \underline{e}_{\theta_i} \quad \text{and} \quad \underline{\Phi}_j = \Phi^r \underline{e}_{r_j} + \Phi^\theta \underline{e}_{\theta_j}$$

Differences

Simulations  
Scalar  
Vectorial  
**Gresho**

Conclusions

Fig.: Density profiles for IC,  
cartesian and polar :  
 $N_\theta = 4$

- Even if  $N_\theta$  is small, polar results close to stationary solution.
- Cartesian does not show good results when  $N_\theta$  is small : profile different to stationary condition.  
⇒ Cartesian and polar methods are only equivalent when  $N_\theta$  is large

# Gresho test

Simulations  
Scalar  
Vectorial  
**Gresho**

Conclusions

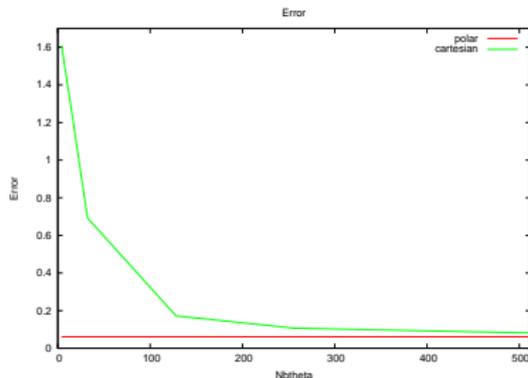

Fig.: Error profiles in function of  $N_\theta$

- Polar error depends only on  $N_r$  and not on  $N_\theta$
- Cartesian error decreases and comes closer to polar curve when  $N_\theta$  raises up.  
⇒ These results confirm that the two methods are equivalent when  $N_\theta$  is large

Vectorial  
Gresho

Conclusions

- Main difference between cartesian and polar methods is the choice of the constants in the cell
- Fluxes computing different between the two methods but equivalent methods when  $N_\theta$  is large
- Polar method independant on  $N_\theta$ , good results even if mesh not refined in  $\theta$

## Perspectives

- Application to toroidal coordinates (3D)
- Application to Element Finite method
